## Exercises

### Section 4.1: 4, 10, 17, 20, 21, 23, 34, 35

4. Verify that the polynomials  $p(x) = 5x^3 - 27x^2 + 45x - 21$ ,  $q(x) = x^4 - 5x^3 + 8x^2 - 5x + 3$

interpolate the data

x	1	2	3	4
y	2	1	6	47

and explain why this does not violate the uniqueness part of the theorem on existence of polynomial interpolation.

**Answer:**

$$p(x) = 5x^3 - 27x^2 + 45x - 21,$$

$$p(1) = 2$$

$$p(2) = 1$$

$$p(3) = 6$$

$$p(4) = 47$$

$$q(x) = x^4 - 5x^3 + 8x^2 - 5x + 3$$

$$q(1) = 2$$

$$q(2) = 1$$

$$q(3) = 6$$

$$q(4) = 47$$

Hence: It does not violate the uniqueness, part of the existence theorem because two polynomials are not of same degree.

10. a. Construct Newton's interpolation polynomial for the data shown.

x	0	2	3	4
y	7	11	28	63

b. Without simplifying it, write the polynomial obtained in nested form for easy evaluation.

Answer:

a.

x	f[ ]	f[ , ]	f[ , , ]	f[ , , , ]
0	7	$f[0,2] = (f[2] - f[0]) / (2 - 0) = 2$	$f[0,2,3] = (f[2,3] - f[0,2]) / (3 - 0) = 5$	$f[0,2,3,4] = (f[2,3,4] - f[0,2,3]) / (4 - 0) = 1$
2	11	$f[2,3] = (f[3] - f[2]) / (3 - 2) = 17$	$f[2,3,4] = (f[3,4] - f[2,3]) / (4 - 2) = 9$	
3	28	$f[3,4] = (f[4] - f[3]) / (4 - 3) = 35$		
4	63			

$$P_3(x) = 7 + 2(x - 0) + 5(x - 0)(x - 2) + 1(x - 0)(x - 2)(x - 3)$$

$$= x^3 - 2x + 7$$

$$b. P_3(x) = 7 + 2(x - 0) + 5(x - 0)(x - 2) + 1(x - 0)(x - 2)(x - 3)$$

$$= 7 + (x - 0)(2 + 5(x - 2) + (x - 2)(x - 3))$$

$$= 7 + (x - 0)(2 + (x - 2)(5 + (x - 3)))$$

$$= 7 + x(2 + (x - 2)(5 + (x - 3)))$$

17. Determine by two methods the polynomial of degree 2 or less whose graph passes through the points (0, 1.1), (1, 2), and (2, 4.2). Verify that they are the same

Answer:

x	f[ ]	f[ , ]	f[ , , ]
0	1.1	$f[0,1] = (f[1] - f[0]) / (1 - 0) = 0.9$	$f[0,1,2] = (f[1,2] - f[0,1]) / (2 - 0) = 0.65$
1	2	$f[1,2] = (f[2] - f[1]) / (2 - 1) = 2.2$	
2	4.2		

$$P(x) = 1.1 + 0.9(x - 0) + 0.65(x - 0)(x - 1)$$

$$= 1.1 + 0.25x + 0.65x^2$$

20. Without using a divided-difference table, derive and simplify the polynomial of least degree that assumes these values:

x	-2	-1	0	1	2
y	2	14	4	2	2

Answer:

$$\begin{aligned}
l_0(x) &= \frac{(x-x_1) \cdot (x-x_2) \cdot (x-x_3) \cdot (x-x_4)}{(x_0-x_1) \cdot (x_0-x_2) \cdot (x_0-x_3) \cdot (x_0-x_4)} = \frac{(x+1)(x)(x-1)(x-2)}{24} \\
l_1(x) &= \frac{(x-x_0) \cdot (x-x_2) \cdot (x-x_3) \cdot (x-x_4)}{(x_1-x_0) \cdot (x_1-x_2) \cdot (x_1-x_3) \cdot (x_1-x_4)} = \frac{-(x+2)(x)(x-1)(x-2)}{6} \\
l_2(x) &= \frac{(x-x_0) \cdot (x-x_1) \cdot (x-x_3) \cdot (x-x_4)}{(x_2-x_0) \cdot (x_2-x_1) \cdot (x_2-x_3) \cdot (x_2-x_4)} = \frac{(x+2)(x+1)(x-1)(x-2)}{4} \\
l_3(x) &= \frac{(x-x_0) \cdot (x-x_1) \cdot (x-x_2) \cdot (x-x_4)}{(x_3-x_0) \cdot (x_3-x_1) \cdot (x_3-x_2) \cdot (x_3-x_4)} = \frac{(x+2)(x+1)(x)(x-2)}{-6} \\
l_4(x) &= \frac{(x-x_0) \cdot (x-x_1) \cdot (x-x_2) \cdot (x-x_3)}{(x_4-x_0) \cdot (x_4-x_1) \cdot (x_4-x_2) \cdot (x_4-x_3)} = \frac{(x+2)(x+1)(x)(x-1)}{24}
\end{aligned}$$

$$\begin{aligned}
p(x) &= \sum_{i=0}^n l_i(x) f(x_i) = 2 \frac{(x+1)(x)(x-1)(x-2)}{24} + 14 \frac{-(x+2)(x)(x-1)(x-2)}{6} + 4 \frac{(x+2)(x+1)(x-1)(x-2)}{4} + \\
&\quad 2 \frac{(x+2)(x+1)(x)(x-2)}{-6} + 2 \frac{(x+2)(x+1)(x)(x-1)}{24} = \\
&= \frac{(x+1)(x)(x-1)(x-2)}{12} + 7 \frac{-(x+2)(x)(x-1)(x-2)}{3} + (x+2)(x+1)(x-1)(x-2) + \\
&\quad - \frac{(x+2)(x+1)(x)(x-2)}{3} + \frac{(x+2)(x+1)(x)(x-1)}{12} \\
&= 4 - 8x + \frac{11x^2}{2} + 2x^3 - \frac{3x^4}{2}
\end{aligned}$$

21. (Continuation) Find a polynomial that takes the values shown in the preceding problem and has at  $x = 3$  the value 10. Hint: Add a suitable polynomial to the  $p(x)$  of the previous problem.

Answer:

$$q(x) = p(x) + c(x+2)(x+1)(x)(x-1)(x-2)$$

$$q(3) = p(3) + 120c$$

$$\text{We have } p(3) = -38 \text{ and } q(3) = 10$$

$$\text{Then } q(3) = p(3) + 120c$$

$$10 = -38 + 120c \text{ then } c = 2/5$$

$$\text{Now: } q(x) = p(x) + c(x+2)(x+1)(x)(x-1)(x-2)$$

$$q(x) = 4 - 8x + \frac{11x^2}{2} + 2x^3 - \frac{3x^4}{2} + \frac{2}{5}(x+2)(x+1)x(x-1)(x-2)$$

$$\text{Hence, } q(x) = 4 - \frac{32}{5}x + \frac{11}{2}x^2 - \frac{3}{2}x^4 + \frac{2}{5}x^5$$

23. Form a divided-difference table for the following and explain what happened

$x$	1	2	3	1
$y$	3	5	5	7

Answer:

x	f[ ]	f[ , ]	f[ , , ]	f[ , , , ]
1	3	$f[1,2]=(5-3)/(2-1)=2$	$f[1,2,3] = (0-2)/(3-1) = -1$	$f[1,2,3,1] = (1+1)/(1-1)$ = undefined
2	5	$f[2,3] = (5-5)/(3-2) = 0$	$f[2,3,1] = (-1-0)/(1-2) = 1$	
3	5	$f[3,1] = (7-5)/(1-3) = -1$		
1	7			

We cannot division by zero since the nodes are not unique. Interpolating polynomials are functions, but the give data set is not from a function, but a relation

34. Write the Lagrange form (1) of the interpolating polynomial of degree at most 2 that interpolates f(x) at x<sub>0</sub>, x<sub>1</sub>, and x<sub>2</sub>, where x<sub>0</sub> < x<sub>1</sub> < x<sub>2</sub>.

Answer:

$$p(x) = \sum_{i=0}^n l_i(x) f(x_i)$$

$$l_i(x) = \prod_{j \neq i, j=0}^n \frac{x - x_j}{x_i - x_j}$$

$$l_0(x) = \frac{(x - x_1) \cdot (x - x_2)}{(x_0 - x_1) \cdot (x_0 - x_2)}$$

$$l_1(x) = \frac{(x - x_0) \cdot (x - x_2)}{(x_1 - x_0) \cdot (x_1 - x_2)}$$

$$l_2(x) = \frac{(x - x_0) \cdot (x - x_1)}{(x_2 - x_0) \cdot (x_2 - x_1)}$$

$$p(x) = f(x_0)l_0(x) + f(x_1)l_1(x) + f(x_2)l_2(x)$$

$$p(x) = f(x_0) \frac{(x - x_1) \cdot (x - x_2)}{(x_0 - x_1) \cdot (x_0 - x_2)} + f(x_1) \frac{(x - x_0) \cdot (x - x_2)}{(x_1 - x_0) \cdot (x_1 - x_2)} + f(x_2) \frac{(x - x_0) \cdot (x - x_1)}{(x_2 - x_0) \cdot (x_2 - x_1)}$$

35. (Continuation) Write the Newton form of the interpolating polynomial p<sub>2</sub>(x), and show that it is equivalent to the Lagrange form.

Answer:

$$p(x) = \sum_{i=0}^n f[x_0, x_1, x_2, x_3, \dots, x_n] \prod_{j=0}^{i-1} (x - x_j)$$

$$p(x) = f(x_0) + \frac{f(x_1) - f(x_0)}{x_1 - x_0} (x - x_0) + \frac{1}{x_2 - x_0} \left( \frac{f(x_2) - f(x_1)}{x_2 - x_1} - \frac{f(x_1) - f(x_0)}{x_1 - x_0} \right) (x - x_0)(x - x_1)$$

$$p(x) = f(x_0) + \frac{f(x_1) - f(x_0)}{x_1 - x_0}(x - x_0) + \frac{1}{x_2 - x_0} \left( \frac{f(x_2) - f(x_1)}{x_2 - x_1} - \frac{f(x_1) - f(x_0)}{x_1 - x_0} \right) (x - x_0)(x - x_1)$$

$$p(x) = f(x_0) \left( 1 - \frac{(x - x_0)}{x_1 - x_0} + \frac{(x - x_0)(x - x_1)}{x_1 - x_0} \right) + f(x_1) \left( \frac{(x - x_0)}{x_1 - x_0} - \frac{(x - x_0)(x - x_1)}{(x_2 - x_1)(x_2 - x_0)} - \frac{(x - x_0)(x - x_1)}{(x_1 - x_0)(x_2 - x_0)} \right) + f(x_2) \left( \frac{(x - x_0)(x - x_1)}{(x_2 - x_1)(x_2 - x_0)} \right)$$

$$p(x) = f(x_0) \frac{(x - x_1) \cdot (x - x_2)}{(x_0 - x_1) \cdot (x_0 - x_2)} + f(x_1) \frac{(x - x_0) \cdot (x - x_2)}{(x_1 - x_0) \cdot (x_1 - x_2)} + f(x_2) \frac{(x - x_0) \cdot (x - x_1)}{(x_2 - x_0) \cdot (x_2 - x_1)}$$

From Lagrange:

$$q(x) = f(x_0)l_0(x) + f(x_1)l_1(x) + f(x_2)l_2(x)$$

$$q(x) = f(x_0) \frac{(x - x_1) \cdot (x - x_2)}{(x_0 - x_1) \cdot (x_0 - x_2)} + f(x_1) \frac{(x - x_0) \cdot (x - x_2)}{(x_1 - x_0) \cdot (x_1 - x_2)} + f(x_2) \frac{(x - x_0) \cdot (x - x_1)}{(x_2 - x_0) \cdot (x_2 - x_1)}$$

Now we can consider  $p(x) = q(x)$ .

Hence, Newton form of the interpolating polynomial  $p_2(x)$ , and it is equivalent to the Lagrange form.

## Section 4.2: 6, 7, 10, 11

6. How accurately can we determine  $\sin x$  by linear interpolation, given a table of  $\sin x$  to ten decimal places, for  $x$  in  $[0, 2]$  with  $h = 0.01$ ?

Answer:

### Second Interpolation Error Theorem

Let  $f$  be a function such that  $f^{(n+1)}$  is continuous on  $[a, b]$  and satisfies  $|f^{(n+1)}(x)| \leq M$ . Let  $p$  be the polynomial of degree  $\leq n$  that interpolates  $f$  at  $n + 1$  equally spaced nodes in  $[a, b]$ , including the endpoints. Then on  $[a, b]$ ,

$$|f(x) - p(x)| \leq \frac{1}{4(n+1)} M h^{n+1} \quad (6)$$

where  $h = (b - a)/n$  is the spacing between nodes.

$$f(x) = \sin x$$

$$f'(x) = \cos x$$

$$f''(x) = -\sin x$$

$$|f''(x)| \leq 1 = M$$

$$|f(x) - p(x)| \leq \frac{1}{4(n+1)} M h^{n+1}$$

$h = (b - a)/n$  is space between nodes. Since we want to approximate  $f(x) = \sin x$  linear interpolation. We have  $n = 1$

$$|f(x) - p(x)| \leq \frac{1}{4(n+1)} M h^{n+1} = \frac{1 \cdot (0.01)^{1+1}}{4(1+1)} = 1.25 \cdot 10^{-5}$$

7. (Continuation) Given the data

$x$	$\sin x$	$\cos x$
0.70	0.64421 76872	0.76484 21873
0.71	0.65183 37710	0.75836 18760

$$\sin(0.705) \approx 0.6442176872 + \frac{0.6518337710 - 0.6442176872}{0.71 - 0.7} (0.705 - 0.7) \approx 0.6480258$$

$$p(x) = f(x_0) + \frac{f(x_1) - f(x_0)}{x_1 - x_0} (x - x_0)$$

$$\sin(0.705) \approx 0.6442176872 + \frac{0.6518337710 - 0.6442176872}{0.71 - 0.7} (0.705 - 0.7) \approx 0.6480258$$

$$\cos(0.702) \approx 0.7648421873 + \frac{0.7583618760 - 0.7648421873}{0.71 - 0.7} (0.702 - 0.7) \approx 0.7635461$$

Using direct trigonometry computation:

$$\sin(0.705) = 0.6480338$$

$$\cos(0.702) = 0.7635522$$

$$\text{Error on sin} = |0.6480338 - 0.6480258| = 8.1 \cdot 10^{-6}$$

$$\text{Error on cos} = |0.7635461 - 0.7635522| = 6.123 \cdot 10^{-6}$$

10. Let the function  $f(x) = \ln x$  be approximated by an interpolation polynomial of degree 9 with ten nodes uniformly distributed in the interval  $[1, 2]$ . What bound can be placed on the error?

**Answer:**

$$n = 9$$

$$|f(x) - p(x)| \leq \frac{1}{4(n+1)} M h^{n+1}$$

Since  $f(x) = \ln x$  and  $x \in [1, 2]$

$$|f'(x)| = |x^{-1}|$$

$$|f''(x)| = |-x^{-2}|$$

$$|f'''(x)| = |2x^{-3}|$$

....

$$|f^{(10)}(x)| = |9!x^{-10}|$$

$$\text{With } x^{-10} \leq 1 \text{ then } |f^{(10)}(x)| \leq 9! = M$$

$$|f(x) - p(x)| \leq \frac{1}{4(9+1)} (9!) \left(\frac{2-1}{9}\right)^{9+1} \approx 2.6018 \cdot 10^{-6}$$

11. In the first theorem on interpolation errors, show that if  $x_0 < x_1 < \dots < x_n$  and  $x_0 < x < x_n$ , then  $x_0 < \xi < x_n$ .

**Answer:**

Define  $x_0 < x < x_n$ ,

#### INTERPOLATION ERRORS I

If  $p$  is the polynomial of degree at most  $n$  that interpolates  $f$  at the  $n+1$  distinct nodes  $x_0, x_1, \dots, x_n$  belonging to an interval  $[a, b]$  and if  $f^{(n+1)}$  is continuous, then for each  $x$  in  $[a, b]$ , there is a  $\xi$  in  $(a, b)$  for which

$$f(x) - p(x) = \frac{1}{(n+1)!} f^{(n+1)}(\xi) \prod_{i=0}^n (x - x_i) \quad (2)$$

$$w(t) = \prod_{i=0}^n (t - x_i) \quad (\text{polynomial in the variable } t)$$

$$c = \frac{f(x) - p(x)}{w(x)} \quad (\text{constant})$$

$$\varphi(t) = f(t) - p(t) - cw(t) \quad (\text{function in the variable } t)$$

Where  $p(t)$  is the polynomial degree at most  $n$  that interpolates  $n+1$  points  $x_0$  through  $x_n$  evaluated with  $f(x)$ .

Note also that  $\varphi$  takes the value 0 at the  $n+2$  points  $x_0, x_1, \dots, x_n$ , and  $x$ . Now invoke Rolle's Theorem, \* which states that between any two roots of  $\varphi$ , there must occur a root of  $\varphi'$ . Thus,  $\varphi$  has at least  $n+1$  roots. By similar reasoning,  $\varphi'$  has at least  $n$  roots,  $\varphi''$  has at least  $n-1$  roots, and so on. Finally, it can be inferred that  $\varphi^{(n+1)}$  must have at least one root. Let  $\xi$  be a root of  $\varphi^{(n+1)}$ . All the roots being counted in this argument are in  $(a, b)$ . Thus,  $\xi$  between  $x_0$  and  $x_n$ . Thus  $x_0 < \xi < x_n$ .

#### Computing Exercises

Section 4.2: 1, 2

1. Using 21 equally spaced nodes on the interval  $[-5, 5]$ , find the interpolating polynomial  $p$  of degree 20 for the function  $f(x) = (x^2 + 1)^{-1}$ . Print the values of  $f(x)$  and  $p(x)$  at 41 equally spaced points, including the nodes. Observe the large discrepancy between  $f(x)$  and  $p(x)$ .

Answer:

Mathlab code:

```
close all
clc

x = linspace(-5,5,21);
fx = 1./(x.^2+1);
```

```

n = 20;
p = polyfit(x,fx,n);    % interpolating polynomial p of degree 20 for the function f
(x)
x = linspace(-5,5,41);
fx = 1./(x.^2+1);
px = polyval(p,x);      % Count p(x)

fprintf("\nDisplay lists fx || px\n")
[fx' px']

figure;plot(x,fx)
hold on
plot(x,px)
legend('f(x)', 'p(x)')
ylim([-1 4.5])

```

Display:

**Another way to code:**

```
clc

f=@(x) (x.^2+1).^(-1);

%create 21 point
x=linspace(-5,5,21);

y=fun(x);

%function to interpolate values
array=coef(x,y);

%create 41 point
x_p=linspace(-5,5,41);

fprintf('    Index |x_values |Actual_values |interpolated values |abs difference\n');

for i=1:1:length(x_p)
```

```

x_p_Index=x_p(i);

%interpolate values

inter_value=Evaluation(x,array,x_p_Index);

Actual_value=fun(x_p_Index);
% Display

fprintf('%5.0f %10.5f %15.5f %15.5f\n',i,x_p_Index,Actual_value,inter_value,abs(Actual_value-inter_value));

end

% Get funtion coef mean a given function to interpolate values
function [array]=coef(x,y)

n=length(x);

m=length(y);

if n~=m,error('same length vector applicable');end

F=zeros(n,n);

F(:,1)=y';

for j=2:n
    for i=1:(n-j+1)
        F(i,j)=(F(i+1,j-1)-F(i,j-1))/(x(i+j-1)-x(i));
    end
end

array=F(1,:);

end

function inter_value=Evaluation(x,array,x_p_Index)

%Performs approximation of the values

z=length(array);

sum=0;

for i=1:z

    value_prodx=1;

```

```

for j=1:i-1

value_prodx=value_prodx*(x_p_Index-x(j));

end

sum=sum+array(i)*value_prodx;

end

inter_value=sum;

end

```

2. (Continuation) Perform the experiment in the preceding computer problem, using Chebyshev nodes  $x_i = 5 \cos(i\pi/20)$ , where  $0 \leq i \leq 20$ , and nodes  $x_i = 5 \cos[(2i + 1)\pi/42]$ , where  $0 \leq i \leq 20$ . Record your conclusions.

**Answer:**

Mathlab code:

```
clc
```

```
f=@(x) (x.^2+1).^(-1);
```

```
i = 0:1:20;
```

```
c_p = 5*cos(i*pi/20);
```

```
x_p = linspace(-5,5,20);
```

```
ChebyshevInterpolate(f,c_p,x_p);
```

```
function ChebyshevInterpolate(fun,c_p,x_p)
```

```
n =length(c_p);
```

```
T = zeros(n,n);
```

```
F = zeros(n,1);
```

```
for i = 1:1:n
```

```
    c_p_index = c_p(i);
```

```
    for j = 1:1:n
```

```
        if j ==1
```

```
            T(i,j)=1;
```

```
        else
```

```
            T(i,j) = chebyshevT(j-1,c_p_index);
```

```
        end
```

```
    end
```

```
    F(i) = fun(c_p_index);
```

```
end
```

```
coeff = T\F;
```

```
fprintf('    Index      Exact      Interpolated      Difference(Error)\n');
```

```
for i = 1:1:length(x_p)
```

```
    sum = coeff(1);
```

```
    x_index = x_p(i);
```

```
    for j = 2:1:n
```

```

        Tj = chebyshevT(j-1,x_index);
        sum = sum + coeff(j)*Tj;
    end
    y_p_c = sum;
    y_p_e = fun(x_index);
    fprintf('%5.0f %15.5f %15.5f %15.5f\n',i,y_p_e,y_p_c,abs(y_p_e - y_p_c));

end
end

```
